

AI Usage Notes

Project

ServeNear MVP

Purpose of AI Use

AI was used as a coding and documentation assistant to help turn the existing UX prototype and product requirements into a working MVP.

The AI supported the development process by helping with planning, code structure, component creation, debugging guidance and documentation.

How AI Was Used

AI was used to support:

- Turning UX requirements into development tasks
 - Creating the React project structure
 - Planning the MVP in small build slices
 - Writing reusable components
 - Creating customer, provider and admin pages
 - Creating localStorage helper functions
 - Implementing mock authentication
 - Implementing booking, messaging and review flows
 - Creating role-based routing
 - Writing README and handover documentation
-

Human Decisions

The product direction, target users, UX decisions, feature prioritisation and final design decisions were based on the ServeNear project research and internship deliverables.

AI was used to assist with implementation, but final review and testing were completed by the project owner.

AI Development Approach

The MVP was built in small sections instead of asking AI to generate the full app at once.

The build process followed this pattern:

1. Define the feature slice.
2. Add or update specific files.
3. Test the feature.
4. Fix issues.
5. Move to the next slice.

This helped reduce errors and made the project easier to understand and control.

What AI Did Not Do

AI did not:

- Conduct the original user research
 - Make final product decisions independently
 - Validate real user behaviour
 - Replace manual testing
 - Provide production-level security review
 - Connect a real backend database
 - Deploy the application
-

Current AI-Assisted Areas

The following areas were created with AI support:

- React page structure
- Reusable UI components
- Mock data setup
- localStorage utilities
- Mock authentication
- Protected routing
- Booking flow
- Provider job management
- Messaging flow
- Review flow
- Admin dashboard
- QA checklist
- Documentation files

Risks and Considerations

Because AI was used to assist with development, the code should be reviewed before any real production use.

Important areas for future review include:

- Authentication security
- Role permissions
- Database rules
- Privacy and data protection
- Input validation
- Error handling
- File upload security
- Payment security
- Accessibility testing

Final Note

AI accelerated the development of the ServeNear MVP, but the project still requires human testing, review and backend implementation before it can be used as a real production platform.
